

**LangChain** is an open-source framework written in Python and JavaScript designed to simplify the development of applications powered by Large Language Models (LLMs). It functions as an orchestration layer that streamlines prompt management, connects multiple models, handles system memory, and links LLMs to external APIs and vector databases. [[1](#), [2](#), [3](#)]

### Core Ecosystem Packages

The Python framework is broken down into modular packages to maintain lightweight installations: [[1](#), [2](#), [3](#)]

- `langchain-core`: Houses base abstractions and core interfaces for components.
- `langchain`: Contains the main cognitive architecture patterns, tools, and pre-built agents.
- `langchain-community`: Community-maintained third-party integrations and components.
- `langchain-text-splitters`: Dedicated utilities for cutting and processing long documents. [[1](#), [2](#), [3](#), [4](#), [5](#)]

### Key Architecture Components

- **Models**: Standardized interfaces to interact with various LLM providers (e.g., Anthropic, OpenAI, Google) via a unified formatting logic.
